(a) Functional description

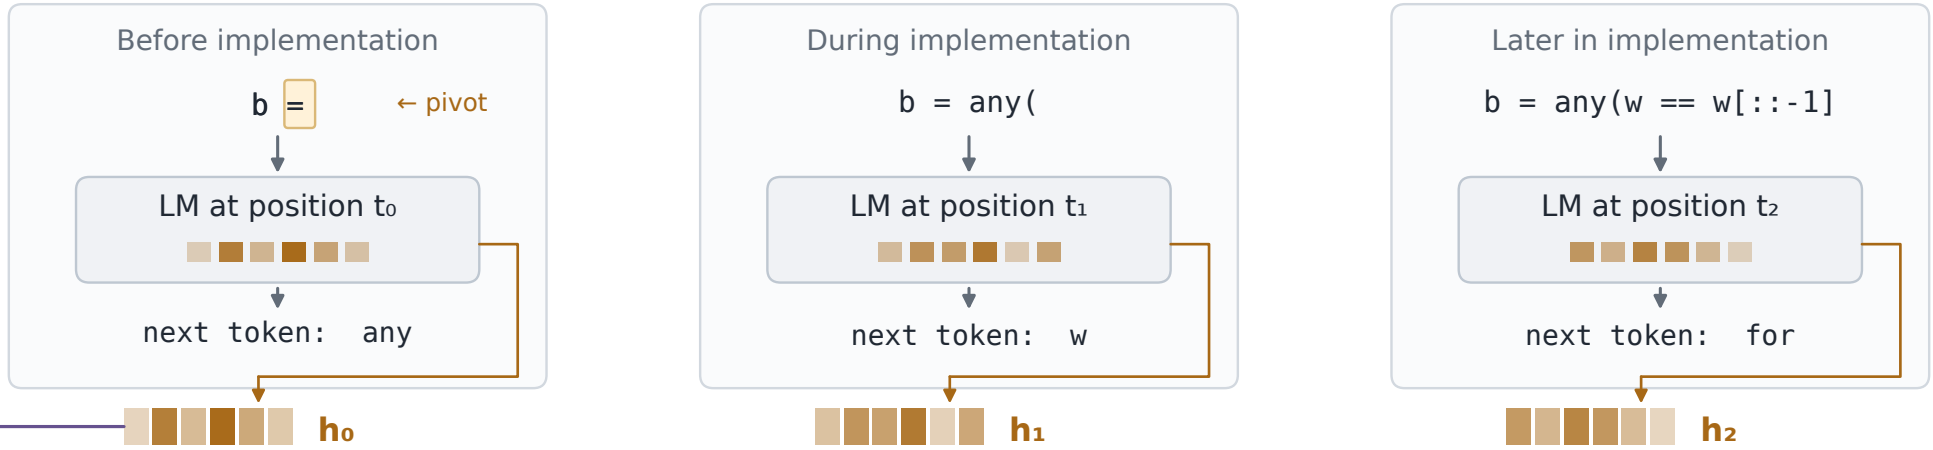

SCHEMATIC

One sub-goal: check whether any word is a palindrome

Select a goal before acting → Act using suitable means → Continue pursuing the goal

(b) LLM implementation

Task: write a Python function that checks whether any word is a palindrome.

Selected head outputs
Cache h_0 once; inject it into separate runs

Temporal persistence: goal-related content across positions

Readout before action

Probe: “What operation are you performing?”

“Check whether any word is a palindrome.”

Plasticity: the same operation in C++

```
return std::any_of(words.begin(), words.end(),
  [](const auto& w) { return std::equal(
    w.begin(), w.end(), w.rbegin()); });
```

Illustrative code and readouts. Shared color denotes goal content, not an unchanged stored vector.
